

<b>Chapter 5: Work, Energy and Power</b>	
<ul style="list-style-type: none"> <li>- Work</li> <li>- Energy conversion and conservation</li> <li>- Potential energy and kinetic energy</li> <li>- Power</li> </ul>	
<b>a.</b>	<b>Show an understanding of the concept of work in terms of the product of a force and displacement in the direction of the force.</b>
<b>b.</b>	<b>Calculate the work done in a number of situations including the work done by a gas which is expanding against a constant external pressure: <math>W = p\Delta V</math>.</b>
	<p><b>Work Done by a force</b> is defined as the product of the force and displacement (of its point of application) <u>in the direction of the force</u></p> <p style="text-align: center;">ie <math>W = F s \cos \theta</math></p> <p><u>Negative work</u> is said to be done by <math>F</math> if <math>x</math> or its compo. is <u>anti-parallel</u> to <math>F</math></p> <p>If a <u>variable</u> force <math>F</math> produces a displacement in the direction of <math>F</math>, the work done is determined from the <u>area under F-x graph</u>. {May need to find area by "counting the squares". }</p>
<b>c.</b>	<b>Give examples of energy in different forms, its conversion and conservation, and apply the principle of energy conservation to simple examples.</b>
	<p>By Principle of Conservation of Energy,</p> <p><b>Work Done on a system =</b>  <b>KE gain + GPE gain + Thermal Energy generated {ie Work done against friction}</b></p>
<b>d.</b>	<b>Derive, from the equations of motion, the formula <math>E_k = \frac{1}{2}mv^2</math>.</b>
	<p>Consider a rigid object of mass <math>m</math> that is initially at rest. To accelerate it uniformly to a speed <math>v</math>, a constant net force <math>F</math> is exerted on it, parallel to its motion over a displacement <math>s</math>.</p> <p>Since <math>F</math> is constant, acceleration is constant,</p> <p>Therefore, using the equation: <math>v^2 = u^2 + 2 a s</math>,  <math>a s = \frac{1}{2} (v^2 - u^2)</math></p> <p>Since kinetic energy is equal to the work done on the mass to bring it from rest to a speed <math>v</math>,</p> <p>The kinetic energy, <math>E_k</math> = Work done by the force <math>F</math>  = <math>F s</math>  = <math>m a s</math>  = <math>\frac{1}{2} m (v^2 - u^2)</math></p>
<b>e.</b>	<b>Recall and apply the formula <math>E_k = \frac{1}{2}mv^2</math>.</b>
	Self-explanatory
<b>f.</b>	<b>Distinguish between gravitational potential energy, electric potential energy and elastic potential energy.</b>
	<p><b>Gravitational potential energy:</b> this arises in a system of <i>masses</i> where there are attractive gravitational forces between them. The gravitational potential energy of an object is the energy it possesses by virtue of its position in a gravitational field.</p> <p><b>Elastic potential energy:</b> this arises in a system of atoms where there are either attractive or repulsive short-range inter-atomic forces between them. (From Topic 4, E. P. E. = <math>\frac{1}{2} k x^2</math>.)</p> <p><b>Electric potential energy:</b> this arises in a system of <i>charges</i> where there are either attractive or repulsive</p>

	electric forces between them.
<b>g.</b>	<b>Show an understanding of and use the relationship between force and potential energy in a uniform field to solve problems.</b>
	The potential energy, $U$ , of a body in a force field {whether gravitational or electric field} is related to the force $F$ it experiences by: $F = -\frac{dU}{dx}$ .
<b>h.</b>	<b>Derive, from the defining equation <math>W = Fs</math> the formula <math>E_p = mgh</math> for potential energy changes near the Earth's surface.</b>
	Consider an object of mass $m$ being lifted vertically by a force $F$ , without acceleration, from a certain height $h_1$ to a height $h_2$ . Since the object moves up at a constant speed, $F$ is equal to $mg$ . The <b>change</b> in potential energy of the mass = Work done by the force $F$ = $F s$ = $F h$ = $m g h$
<b>i.</b>	<b>Recall and use the formula <math>E_p = mgh</math> for potential energy changes near the Earth's surface.</b>
	Self-explanatory
<b>j.</b>	<b>Show an appreciation for the implications of energy losses in practical devices and use the concept of efficiency to solve problems.</b>
	<b>Efficiency:</b> The ratio of (useful) output energy of a machine to the input energy. ie $= \frac{\text{Useful Output Energy}}{\text{Input Energy}} \times 100\% = \frac{\text{Useful Output Power}}{\text{Input Power}} \times 100\%$
<b>k.</b>	<b>Define power as work done per unit time and derive power as the product of force and velocity.</b>
	<b>Power</b> {instantaneous} is defined as the work done per unit time. $P = \frac{\text{Total Work Done}}{\text{Total Time}}$ $= \frac{W}{t}$ Since work done $W = F \times s$ , $P = \frac{F \times s}{t}$ $= F v$ <ul style="list-style-type: none"><li>- for object moving at <u>const speed</u>: <math>F =</math> Total resistive force {equilibrium condition}</li><li>- for object beginning to <u>accelerate</u>: <math>F =</math> Total resistive force <b>+ <math>ma</math></b> {N07P1Q10,N88P1Q5}</li></ul>
